

# Introduction to CUDA

Ben Cumming, CSCS June 17, 2015

# Before We Start

## Quick survey of participants

Would any body like to pair up for the practicals?

• it would be good to form teams that can share C++ and terminal/Linux skills

#### Logging in

Can everybody try to log into Piz Daint?

ssh username@daint

Let us know if you need help

# Why GPUs?

### There is a trend towards more parallelism "on node"

Multi-core CPUs get more cores and wider vector lanes

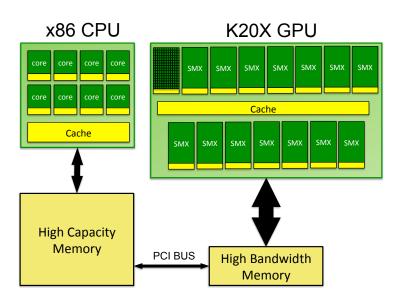

- 16-core×2 thread Haswell processors from Intel
- 12-core×8 thread Power8 processors from IBM

Many-core Accelerators with many highly-specialized cores and high-bandwidth memory

- NVIDIA K20X GPUs with 2688 cores
- Intel KNL with 72 cores × 4 threads

## Most current applications are not designed for many core

- exposing sufficient fine-grained parallelism for multi and many core processors is hard
- new programming models are required
- new algorithms are required
- existing code has to be rewritten or refactored

#### ... and compute nodes are under-utilized

- users are not getting the most out of allocations
- the amount of parallelism on-node is only going to increase!

#### MPI and the free lunch

HPC applications were ported to use the message passing library MPI in the late 90s and early 200s at great cost and effort

- individual nodes with one or two CPUs
- break problem into chunks/sub-domains
- explicit message passing between sub-domains

The "free lunch" was the regular speedup in codes as CPU clock frequencies increased and as the number of nodes in systems increased

 with little/no effort, each new generation of processor bought significant speedups

... but there is no such thing as a free lunch

# How to speed up an application

#### There are 3 ways to increase performance

- 1. increase clock speed
- 2. increase the number of operations per clock cycle
  - e.g. vectorization
  - e.g. multi-core
- 3. don't stall
  - e.g. cache to avoid waiting on memory requests
  - e.g. branch prediction to avoid pipeline stalls

## What about just increasing clock frequency?

The number of operations per second that can be performed is directly proportional to CPU frequency

 increasing frequency is a great way to increase performance

Power consumption is a function of frequency f

$$P_{\text{dynamic}} = CV^2 f$$

However voltage V is proportional to frequency, so power increases super-linearly with clock frequency

 increasing frequency is an even better way to increase power consumption!

#### Clock frequency won't increase

In fact, clock frequencies have been going down as the number of cores increases

- a 4-core Haswell processor at 3.5 GHz (4\*3.5=14 Gops/second) has the same power consumption as a 12-core Haswell at 2.6 GHz (12\*2.6=31 Gops/second)
- a K20X GPU with 2688 CUDA cores runs at 800 MHz

#### Parallelism will increase

- the number of cores in both CPUs and accelerators will continue to increase
- the width of vector lanes in CPUs will increase
  - currently 4 doubles for AVX
  - increase to 8 double for AVX-3 (KNL and Skylake)
- the number of threads per core will increase
  - Haswell supports 2 threads/core
  - KNL supports 4 threads/core
  - Power-8 supports 8 threads/core

### Memory is slow

- memory is much slower than processors
  - for both CPU and GPU the latency of fetching a cache-line from memory is 100s of cyles
  - that is 100s of cycles that the processor is stalled, unable to "work"
  - latency has to be hidden or reduced to minimise stalling

#### CPU solution: deep caches and prefetching

- use fast on-chip memory to **cache** frequently used data
- use hardware to **prefetch** data to cache before it is required

#### GPU solution: over subscribe threads to cores

- schedule many threads per core
- threads that are waiting for data are idle

### TLDR: change because power

Writing good concurrent code for many-core is difficult

- but the days of easy speed up each generation of CPU are over
  - performance gains must not increase power consumption from now on
- to continue improving performance many-core will be required
- this course will be about one type of many-core architecture NVIDIA GPUs
  - both CUDA and OpenACC are GPU-specific
  - but the concepts will be universally applicable to other many-core architectures (e.g. Xeon Phi)

#### Terminology

- the CPU and its memory are called the **host** (because GPUs require a host CPU to coordinate them)
- the GPU and its memory are referred to as the **device**

# Using GPUs in Your Application

#### Libraries

- use an off the shelf solution implemented in a library
- for specific tasks like dense linear algebra and FFTs, libraries are very hard to beat
- e.g. cublas, PETSc, cuFFT

#### Directives

- OpenACC and OpenMP 4 define directives that can be used to instruct the compiler how to generate GPU code
- in theory easy to port codes

#### GPU-specific Languages

- languages designed for GPU programming
- maximum flexibility and performance
- e.g. CUDA and OpenCL
